The strength of wrought iron plates acting as struts, varies approximately as their width and as the cube of their thickness, and inversely as the square of their height or length; corresponding to formulas 31 and 32. To calculate the strength of struts, having the form of angle iron, T iron or double T iron, apply Gordon s formula 40, calling the thickness in the weakest direction; i. e., the direction in which it will give way, and considering separately the various parts into which it will be divided by planes parallel to that in which it would bend, for example, parallel to A B in Fig. 28. Fig; 28. Example. Length 8 . For A B a = 1.80 square inches; for G D a = 2.4 x.6 = 1.44 square inch, t--0.6. By Gordon s formula W = 53,748 pounds. 3D Actual breaking stress = 36,000, Using in the formula 24,000 instead of 36,000 would give the actual results. Experiments are wanting. Experiments by N. Y. C. E. E. give results indicating in the iron used in this form th proper values of g to be 6nly about 24,000. The strut \$ the example, of English crown iron behaved as follows m the experiments.
